

# DEEP LIVE CELL IMAGING IN SUPER RESOLUTION

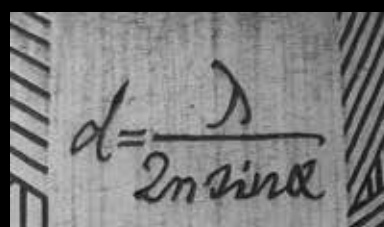

# Super resolution

In theory, super resolution (SR) is **imaging beyond the diffraction limit** (d), defined by Abbe's law as:

$$d = \frac{\lambda}{2NA}$$

or

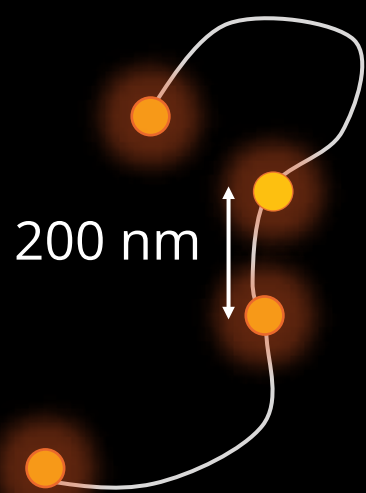

*Ernst Abbe memorial  
Jena, Germany*

Where d is the minimum resolvable distance,  $\lambda$  is the wavelength, NA is the numerical aperture, n is the refractive index and  $\alpha$  is the maximum collection angle.

In practice, SR techniques are those that provide **resolution better than 200 nm...**

Sample

Super resolved image

Diffraction limited image

...when imaged with an objective with high NA and refractive index of oil. Usually, these objectives have high magnification and short working distance (WD).

# SR dependent on NA

According to Abbe's law,  $d = \lambda/2NA$ ,  
the higher the NA, the better the  
resolution.

**NA** defines the  
**angle** of the  
collected light, the  
higher the NA, the  
larger the angle and  
the lower the  
diffraction  
limit (in nm)

Fibroblasts imaged in SR using Point *RE*scan GAIA

# Depth of SR dependent on WD

Objectives with long working distance (WD) have in general lower magnification and lower NA than those with short WD.

**0.8mmWD**

the higher the NA, the shorter the **WD**

**0.3mmWD**

**Image depth 400  $\mu\text{m}$**

**Image depth 83  $\mu\text{m}$**

Living zebrafish imaged in SR using Point *RE*scan GAIA

# Types of SR techniques

Based on resolution, there are two groups of SR techniques:

1. Providing resolution 100-200 nm:

PR (Pixel reassignment)

$d = 120-150 \text{ nm}$

SIM

$d = 100-130 \text{ nm}$

FB (Fluctuation based)

$d = \text{ca. } 150 \text{ nm}$

2. Providing resolution beyond 100 nm:

ExM (Expansion microscopy)

$d = 50 \text{ nm}$

SMLM

$d = 10-20 \text{ nm}$

STED

$d = 50-100 \text{ nm}$

Zhang et al, Curr Protoc Neurosci 2020

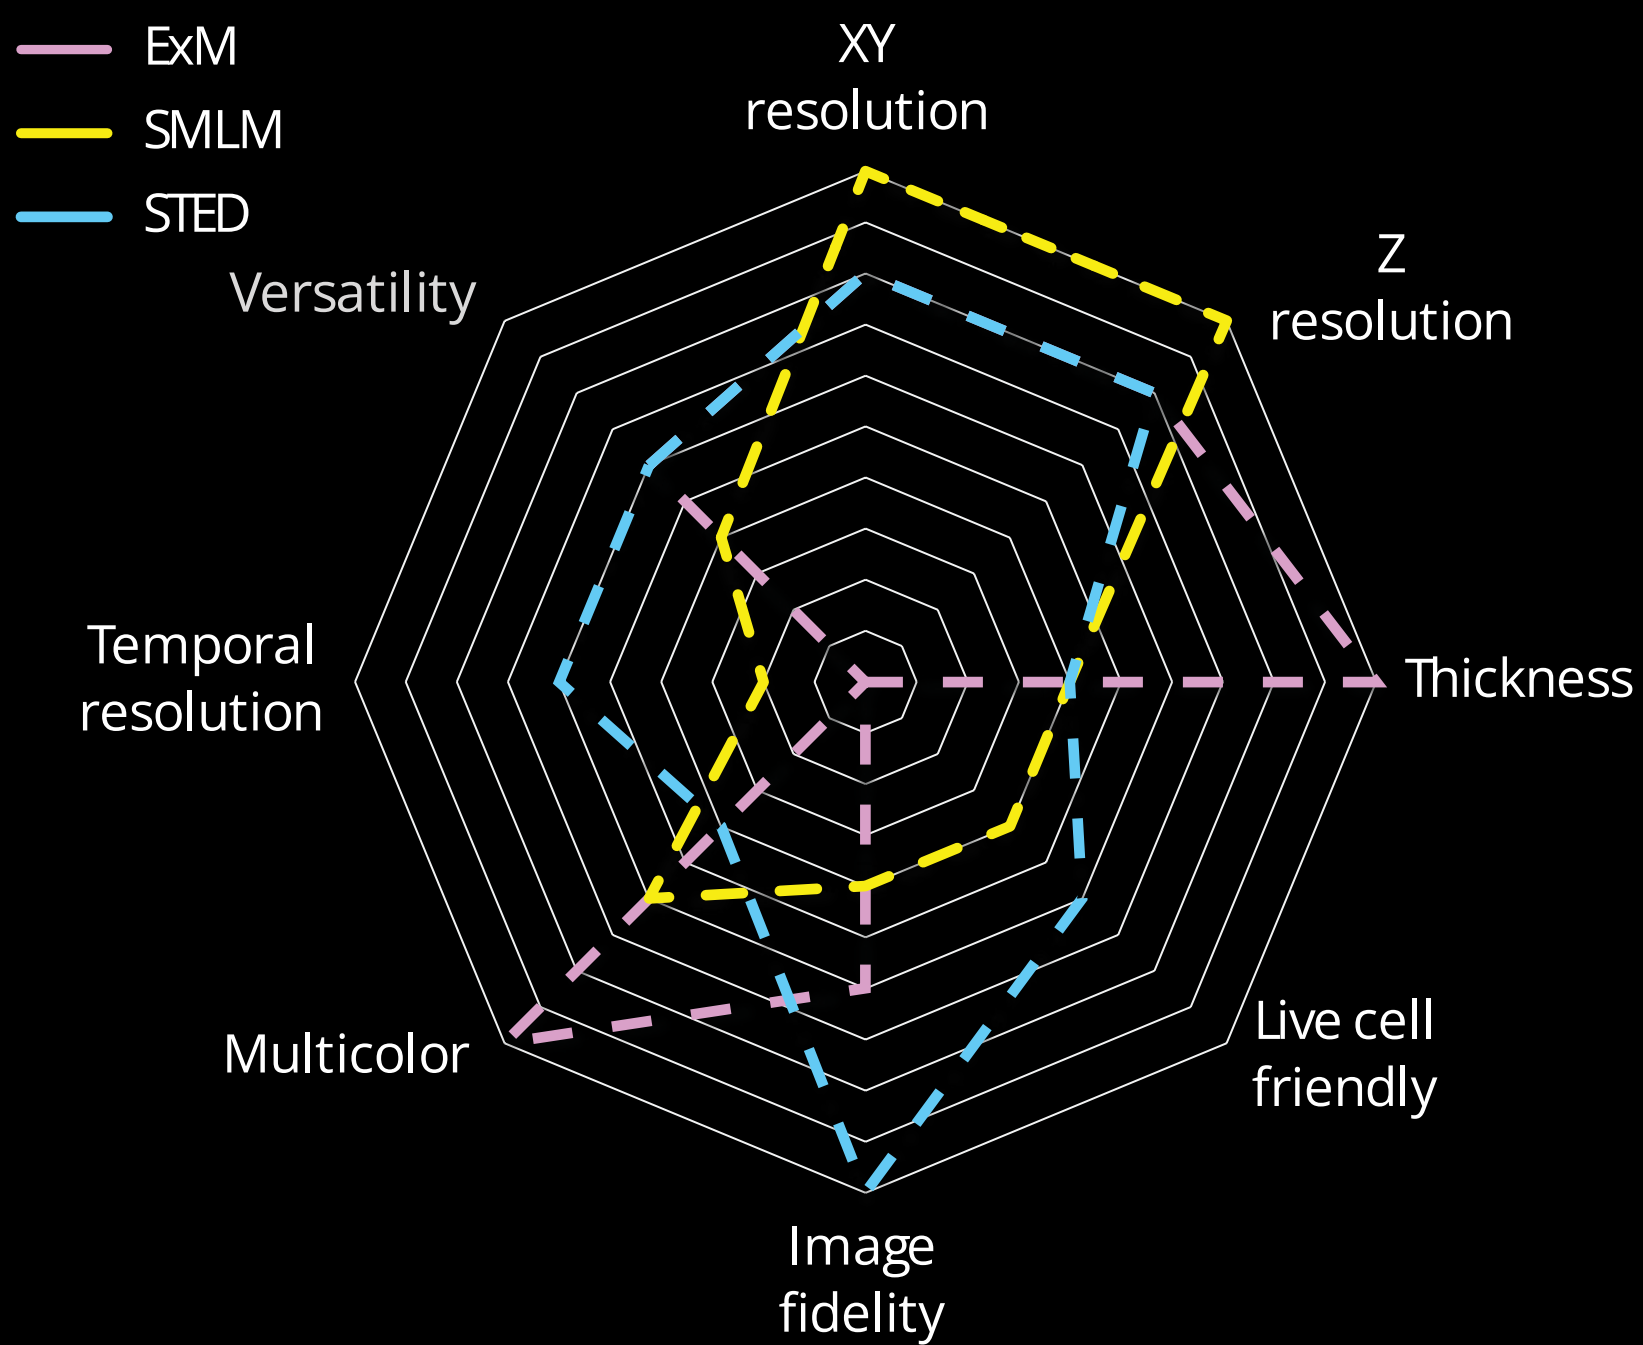

# SR techniques not suitable for living cells

The better the resolution of an SR technique, the less suitable for live cell imaging that technique is.

|      | Live cell friendly  |
|------|---|
| ExM  | 0/5, impossible due to the sample prep  |
| SMLM | 2/5, almost impossible due to the sample prep, long acquisition and high laser powers |
| STED | 3/5, possible only over very short periods due to high laser powers                   |

Jacquemet et al,  
J Cell Sci 2020

# SR techniques for live cell imaging

Among all SR techniques, by far the best ones for live cell imaging are those based on pixel reassignment (**PR**).

|     | Live cell friendly  |
|-----|---|
| PR  | <b>5/5, best suitable for live cell imaging</b>   |
| SIM | 4/5, most common 3D SIM is more phototoxic than TIRF SIM that is incapable for deep imaging |
| FB  | 4/5, phototoxicity varies depending on the method (SOFI, SRRF)                              |

Jacquemet et al,  
J Cell Sci 2020

# Deep live cell imaging using PR techniques

**Point REscan** stands out among pixel reassignment techniques for its advantages in both deep and live cell imaging.

1. Being optimized for the widest range of objectives gives **REscan advantage in deep imaging** as it can use objectives with longer WD.
2. More light through more open pinhole ( $\geq 1.5$  AU) and higher quantum efficiency of a detector (96% QE) give **REscan advantage in live cell imaging**.

*REscan* collects more light without losing resolution.

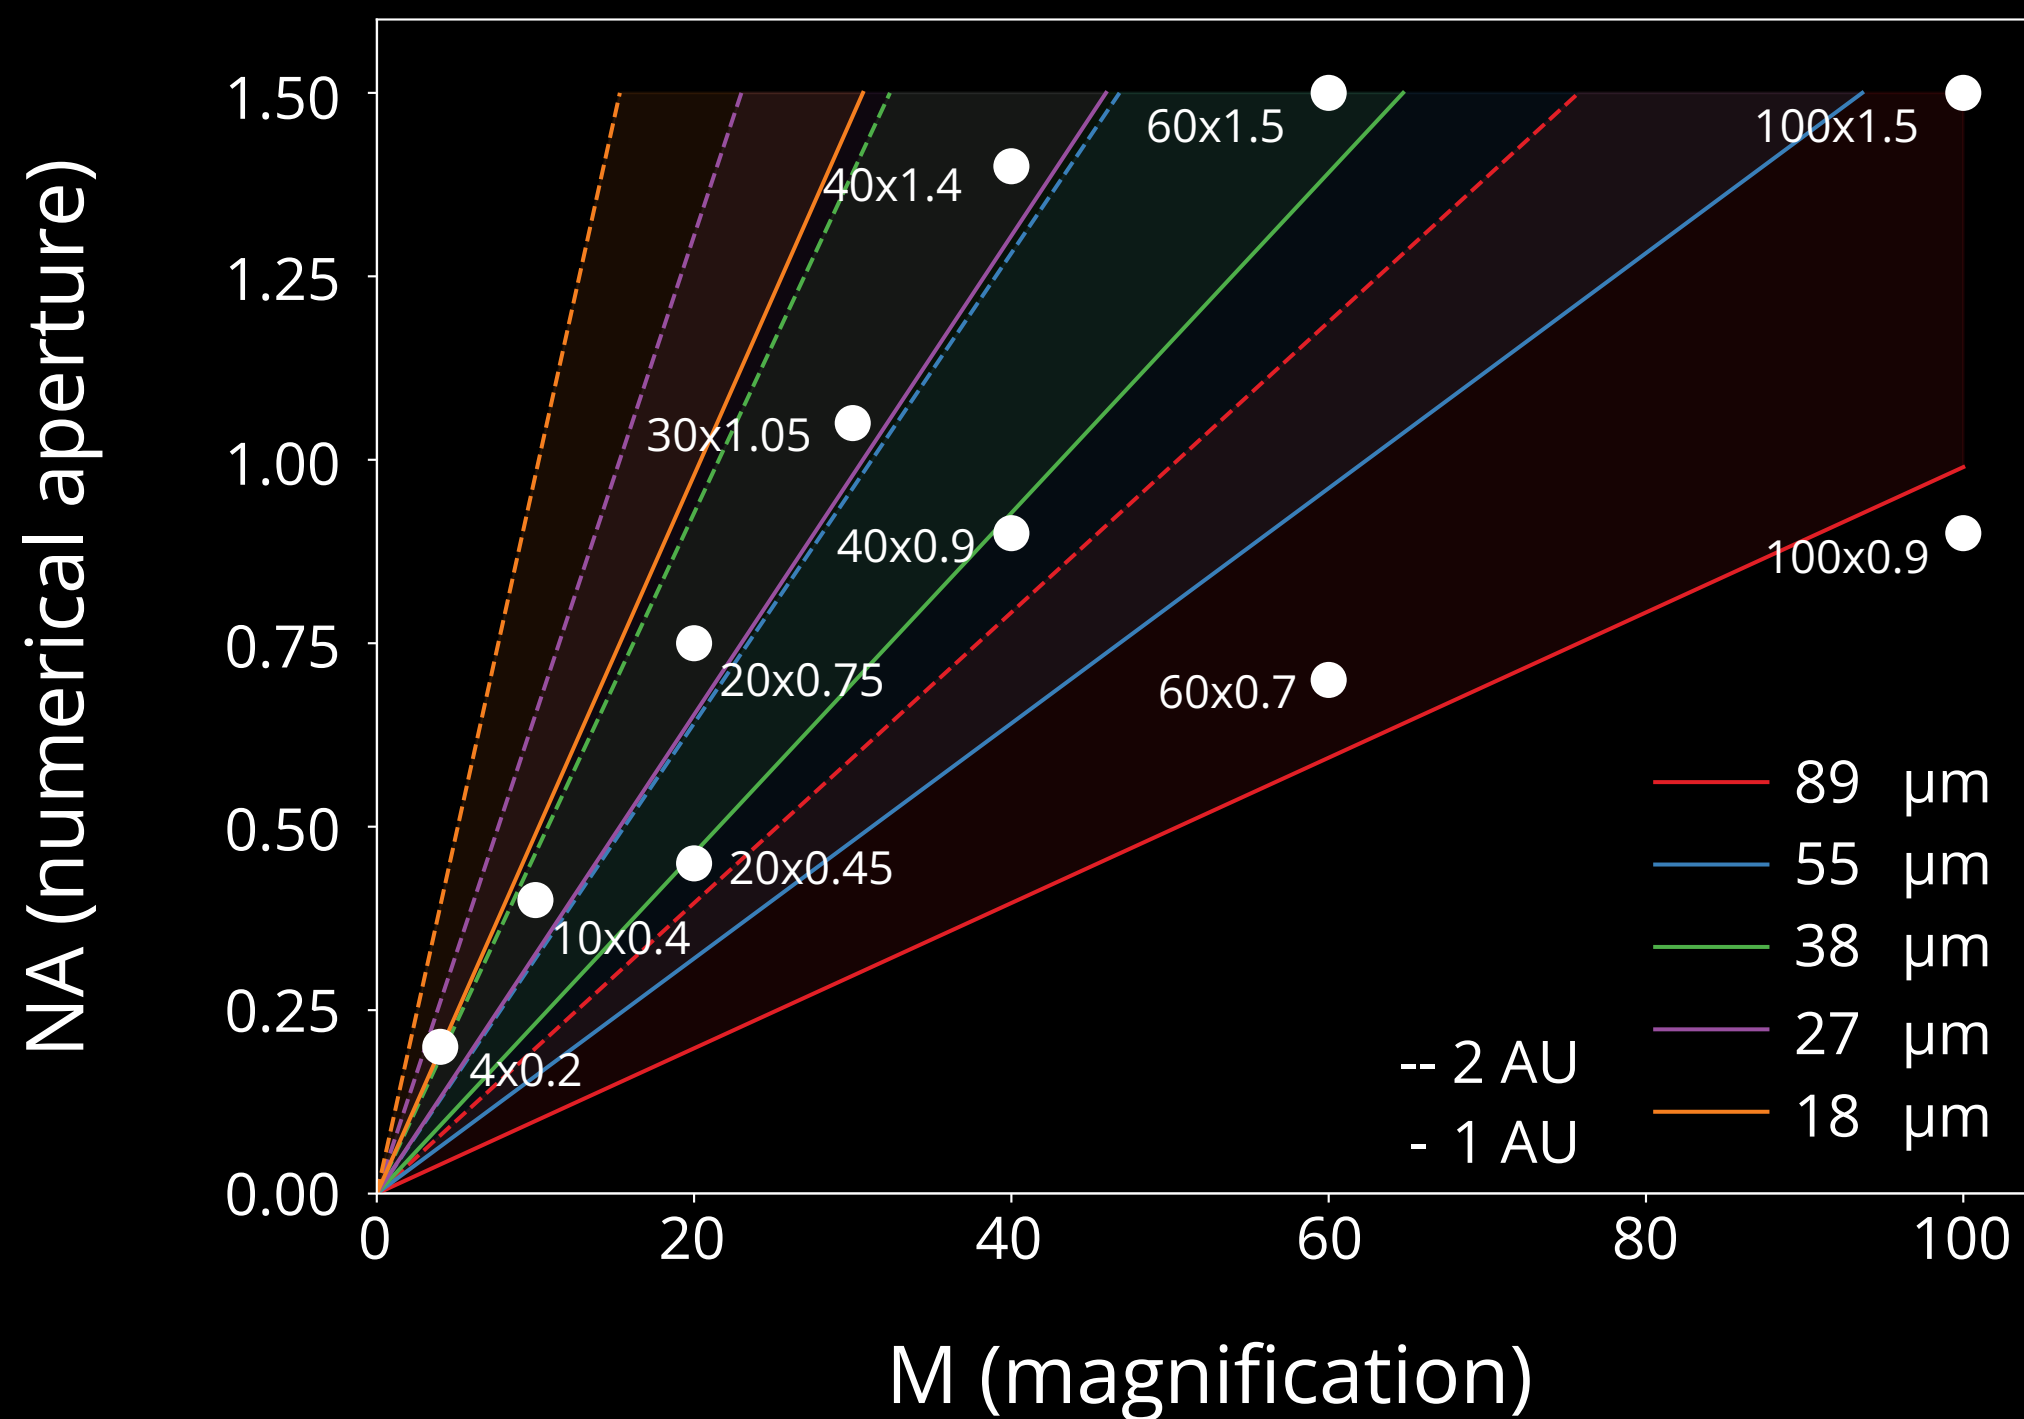

# Deep live cell SR imaging

Solution to NA/WD problem in deep live cell SR imaging is finding the optimal combination of magnification, NA, pinhole size and camera.

GAIA pinhole size chart

**GAIA is the solution that can provide live cell imaging in SR deeper than 500  $\mu\text{m}$  in sample.**
